Author's response

The manuscript has been subjected to changes according to the suggestions and comments of the two referees. We hope that in the current version the paper is now suitable for publication on Ocean Science (OS). The changes performed on the text are reported step-by-step below.

Referee #1

Comments from Referee

The only thing that I can add at this stage is with regard to the Discussion section that after revision has been turned into a separated section. In my opinion, this part is quite weak at the moment because authors only describe the C-CEMS components and the results obtained and this information has already been described in the previous sections of the document. The Discussion (without –s) should place the results obtained in this work in the “global” research context, confirming or refuting what has been described in the literature. The Discussion part should have the style of how Conclusions are presented at the moment, including references. Conclusions, in general terms, should summarize the content and purpose of the paper as well as the importance of the results obtained. I would encourage the authors to rewrite Discussion and Conclusions sections to reinforce the work presented.

Author's response

The Discussion and Conclusions sections have been rewritten as suggested by Referee #1. C-CEMS has been put in the “global” research context and some parts of Conclusions have been moved in Discussion to consider also the future developments regarded to the updating and applications of the observing system. Conclusions section now includes the purpose and the main results of the paper. The main changes are reported in the:

- page 15 in the lines intervals 2-11, 18-21 and 29-32;
- page 16 in the lines intervals 1-2 and 23-32;
- page 17 in the lines intervals 1-9 and 12-25.

The new references related to the topics are included on the:

- page 24 in the lines interval 13-16 (Kourafalou et al., in press);
- page 26 in the lines interval 18-20 (Sayol et al., 2014) and 28-30 (Siddorn et al., 2007);
- page 27 in the lines interval 6-11 (Tintore et al., 2013);
- page 28 in the lines interval 10-12 (Weisberg et al., 2009).
Referee #2

Comments from Referee

Lastly, but importantly, the manuscript in its current form is crippled by disorganization. The Introduction and Results & Discussion sections are sprawling and difficult to follow. I do prefer to see in a scientific paper results and discussion well separated. The Data & physical section is not reasonably clean and is lacking in information, but the Methods & Methodology section is impenetrable with a lack of a simple workflow that could help the reader (Figure 2 is not helping the reader in that direction).

Still I do think there is no discussion in the paper that represent just a extended conclusion. The main question is: what is the scientific question you ask and what is the main advance you get after this paper? This is not clear still within this version. Please also consider that figure 2 is not helping at all in that direction.

So my previous review still holds:

What exactly do we gain from combined temporal C-CEMS approach that we cannot determine, for example, from a classical method? The technological advantage—and whether or not the analysis of that advantage is innovative—depends on the research question. At this stage the paper represent a series of analysis that is unclear how they set up the innovative method.

Author's response

The Introduction and Discussion sections have been changed emphasizing the advantages connected to the use of the observing systems in the analysis of the high spatial and temporal variability of the coastal processes. In particular we report a series of works that encourage to develop coastal observing systems, like C-CEMS, to identify episodic and occasional events that are scarcely identifiable using traditional methods. The figure 2 has been modified in order to better understand the C-CEMS role in the coastal sustainable management.

The main changes are reported in the:

- page 3 in the lines interval 14-33;
- page 4 in the lines interval 1-8;
- page 6 in the lines interval 10-22;
- page 15 in the lines intervals 2-11, 18-21 and 29-32;
- page 16 in the lines intervals 1-2 and 23-32;
- page 17 in the lines interval 1-9;
- page 32 in the lines interval 1-14.
The new references related to the topics are included on the:
- page 23 in the lines interval 9-10 (Glenn et al., 2000) and 14-15 (Haidvogel et al., 2000);
- page 24 in the lines interval 6-9 (Juza et al., in press), 10-12 (Korres and Lascaratos, 2003) and 13-16 (Kourafalou et al., in press);
- page 25 in the lines interval 3-6 (Malone et al., 2014), 17-18 (Oddo et al., 2005), 19-21 (Oddo et al., 2009) and 22-24 (Olita et al., 2012);
- page 26 in the lines interval 18-20 (Sayol et al., 2014) and 28-30 (Siddorn et al., 2007);
- page 27 in the lines interval 1-3 (Smith et al., 1987), 6-11 (Tintore et al., 2013), 12-13 (Tonani et al., 2008) and 14-17 (Tonani et al., 2015);
- page 28 in the lines interval 4-6 (Vidal-Vijande et al., 2011) and 10-12 (Weisberg et al., 2009).

Comments from Referee

Within the study area please consider to insert some key papers related to the dredged sediment management especially considering that you are dealing with a very specific regional area (page 4 line 9):

Author's response

In the Study Area section, we have also considered the dredged sediment management along the Italian coasts including the papers suggested by the referee.
This change is reported at the page 5 in the lines interval 13-15.
The new references related to the topics are included in the:
- page 19 in the lines interval 15-17 (Bigongiari et al., 2015);
- page 20 in the lines interval 8-10 (Cappucci et al., 2011);
- page 22 in the lines interval 1-3 (Cutroneo et al., 2014).

Comments from Referee

Within the the multi-temporal C-CEMS approach to create an observatory and forecast system using also the Earth observation part please consider recent publications:
Filipponi et al., Ten-years sediment dynamics in Northern Adriatic sea investigated through optical remote sensing observations, Geoscience and Remote Sensing Symposium (IGARSS), 2015 IEEE International DOI: 10.1109/IGARSS.2015.7326258

Author's response
In the Satellite observations paragraph, we have considered the recent publications concerning the study of the coastal dynamic processes by EO data.
This change is reported at the page 8 in the lines interval 16-18.
The new references related to the topics are included on the:
- page 23 in the lines interval 1-4 (Filipponi et al., 2015);
- page 25 in the lines interval 9-11 (Manzo et al., 2015).

Comments from Referee
Paragraph 3.
I do not see the importance to be so detailed about several in the Remote sensing part. As an example why adding the ENVI software details? You can do similar analysis with other software unless there is something very peculiar that is not clear. The same comment apply to the data description.
Author's response
In the Satellite observations paragraph, we have eliminated the details regarding the methods used to process the AVHRR and MODIS data.
This change is reported on the page 8 in the lines interval 26-32 and on the page 9 in the lines interval 1-6.

Comments from Referee
Figures:
Please add Lat-Long within figure 1. Most of the readers do not know where Civitavecchia is.
Author's response
The Lat-Long coordinates have been added within the figure 1(B) on the page 30.
Comments from Referee

Figure 2. I do not see a clear explanation of the color and boxes within the block diagram. It is quite difficult to follow and link between the manuscript and the C-CEMS component in the scheme. Whoever wants to replicate the approach could have several problems to do so.

Author's response

At the page 32, the figure 2 and its caption has been modified in order to make it easier the part of C-CEMS components and, at the same time, to emphasize the C-CEMS role in supporting the management of marine environment resources.

In the other part of the manuscript, some technical corrections have been made to improve the structure and organization of the paper.
The Civitavecchia Coastal Environment Monitoring System (C-CEMS): a new tool to analyse the conflicts between coastal pressures and sensitivity areas

Abstract

The understanding of the coastal environment is fundamental for efficiently and effectively facing the pollution phenomena, as expected by Marine Strategy Framework Directive, and for limiting the conflicts between anthropic activities and sensitivity areas, as stated by Maritime Spatial Planning. To address this, the Laboratory of Experimental Oceanology and Marine Ecology developed a multi-platform observing network that has been in operation since 2005 in the coastal marine area of Civitavecchia (Latium, Italy), where multiple uses and high ecological values closely coexist. The Civitavecchia Coastal Environment Monitoring System (C-CEMS), implemented in the current configuration, includes various components allowing to analyse the coastal conflicts by an ecosystem based approach. The long-term observations acquired by the fixed stations are integrated with in-situ data collected for the analysis of the physical, chemical and biological parameters of the water column, sea bottom and pollution sources detected along the coast. The in-situ data, integrated with satellite observations (e.g. temperature, chlorophyll-a and TSM), are used to feed and validate the numerical models, which allow the analysis and forecasting of the dynamics of pollutants dispersion under different conditions. To test the potential capabilities of C-CEMS, two case studies are here reported in this work: 1) the analysis of fecal bacteria dispersion for bathing
water quality assessment and; 2) the evaluation of the effects of the dredged activities on
Posidonia meadows, which make up most of the two sites of community importance located
along the Civitavecchia coastal zone. The simulations outputs results are overlapped
combined with the thematic maps regarding presence of bathing areas and Posidonia oceanica distribution thus giving a first practical tool which could improve the resolution of
in order to solve the conflicts between coastal uses (in terms of stress produced by anthropic
activities) and sensitivity areas.

1 Introduction

Coastal ecosystems are characterized by the spatial and temporal coexistence of multiple uses
connected to many human activities such as aquaculture, energy production, maritime
transport, tourism, and fishery that coexist both spatially and temporally in these areas. The
overlap of such activities and their objectives leads to the generation of has the ability to
create user-user and user-environment conflicts (Douvere, 2008) that result in increasingly
undesirable effects such as loss and destruction of habitat, pollution, climate change, over-fishing, and cumulative threats to the oceans and human health as a whole.

The Integrated Marine Policy (IMP) has faced this issue by the adoption of the Maritime Spatial Planning Directive (MSP, 2014/89/EU) whose main purpose is to promote the sustainable management of uses and conflicts in coastal areas through an ecosystem-based approach. MSP strategy allows to minimize the impacts on sensitivity areas, also enabling the achievement of the Good Environmental Status (GES) by 2020, requested by Marine Strategy Framework Directive (MSFD 2008/56/EC). In the last years a big effort was has been made by the scientific community to provide new approaches for the analysis of GES descriptors like the study of eutrophication (descriptor 5) through satellite ocean color data (Cristina et al., 2015) and the assessment of sea-floor integrity (descriptor 6) by SAR imagery (Pieralice et al., 2014). Important results have were also been obtained by the analysis of both commercial fishes and foodweb (descriptors 3 and 4), to assess the environmental status of European seas (Jayasinghe et al., 2015), and the levels of major contaminants (descriptors 8 and 9) and their pollution effects on aquatic biota (Tornero and Ribera d’Alcalà, 2014).

In keeping line with the holistic approach pursued by nature of the MSFD, the achievement and the maintenance of marine ecological standards need the support of monitoring networks which use L-TER observations and integrate multi-disciplinary datasets, fundamental to forecast specific events (Schofield et al., 2002). However, a recent study by Crise et al. (2015)
revealed gaps of data in the Mediterranean region (South European Seas), highlighting the scarcity, dispersion and heterogeneity of coastal waters datasets. So, it is accordingly necessary to develop observational monitoring systems in the southern European coastal areas capable of collecting both high-resolution and long-term data and building multi-disciplinary datasets.

Recent advances in communication and sensor technology have led to the development of worldwide multi-platform networks that provide a significant amount of data on different spatial and temporal scales for the study of oceanographic processes and marine ecosystem monitoring (Glasgow et al., 2004; Hart and Martinez, 2006; Kröger et al., 2009). These observational systems monitoring tools are especially suited for the monitoring of coastal systems areas (i.e., Chesapeake Bay Observing System, CBOS; Li et al., 2005; Long-term Ecosystem Observatory, LEO-15; Schofield et al., 2002) characterized by high spatial and time variability and affected by strong conflicts between human uses and ecosystem conservation, where many of the processes related to natural or anthropic events (pollution spilling, water discharges, river plume, etc.) are often episodic and occasional, consequently they are scarcely identifiable using traditional methods (Schofield et al., 2002). Only an integrated and multiplatform approach, which combines data and forecast models, allows the characterization of the different events and conflicts in coastal waters (Smith et al., 1987; Glenn et al., 2000; Haidvogel et al., 2000). Improved modeling and real-time sensing capabilities in terms of accuracy and spatial and temporal resolution are required, also in order to respond to both science and societal needs (Tintoré et al., 2013). Particularly, linking observations and models has been recognized to be a critical step to achieve effective integrated ecosystem assessment (Malone et al., 2014). The mathematical models cover a fundamental role in the global and regional ocean forecasting systems since they assimilate the observational data in order to produce reanalysis and forecast products of the most relevant ocean and physical variables (Tonani et al., 2015). Most of regional operational systems in the Mediterranean Sea are included into Mediterranean Forecasting System (MFS) such as the Adriatic Forecasting System (Oddo et al., 2005), the Sicily Channel Regional Model (Olita et al., 2012), the Tyrrenhian Sea Forecasting (Vetrano et al., 2010), the Aegean-Levantine Forecast System (Korres and Lascaratos, 2003) or the Western Mediterranean Operational Forecasting System (Juza et al., in press). Most of MSF products are disseminated by MyOcean project (http://marine.copernicus.eu) which, together with satellite and in-situ observations, developed the pre-operational European Copernicus marine service.
However, several simulations in the Mediterranean Sea are based on basin scale features and metrics (Tonani et al., 2008; Oddo et al., 2009; Vidal-Vijande et al., 2011) partially because of the lack of data at sub-basin scale. A recent study by Crise et al. (2015) revealed gaps of data in the Mediterranean region (South European Seas), highlighting the scarcity, dispersion and heterogeneity of coastal waters datasets. Conversely, the advancement from global to regional and local scale modelling, which is necessary to analyse and forecast the pollution phenomena in coastal areas, is applicable only in the region where a large amount of observing data exists.

As a first step in this direction In this context, the Laboratory of Experimental Oceanology and Marine Ecology developed a multi-platform observing network which has been operating since 2005 in the coastal marine area of Civitavecchia (Italy, Tyrrhenian Sea, Western Mediterranean Sea), critically interested by the presence of many conflicts. This paper presents the C-CEMS as a tool to support the management of conflicts between anthropic uses and sensitivity areas. We It focused on: (1) the functioning of C-CEMS and its components (Section 3); (2) its capabilities in estimating reproducing the dispersion of fecal bacteria for bathing water quality assessment and of dredged fine sediments to evaluate the effects on Posidonia oceanica meadows present in the Sites of Community Importance (SCI) (Section 4); (3) the resulting analysis of "urban discharge - bathing area" and "dredging - SCI" conflicts (Section 5).

2 Study area

The study area is located along the north-east Tyrrhenian coast (Western Mediterranean sea) (Fig. 1A). The circulation of the Tyrrhenian basin is affected by mesoscale and seasonal variability (Hopkins, 1988; Pinardi and Navarra, 1993; Vetrano et al. 2010). The presence of a cyclonic gyre with a very pronounced barotropic component suggests that the wind plays a major role as a forcing agent (Pierini and Simioli, 1998). Like most of the Italian coast, the north-east Tyrrhenian one counts many tourist and industrial areas primarily used for maritime transport and energy production, involving an intense exploitation of marine resources. Nevertheless, it houses several biodiversity hotspots and marine protected areas for the conservation of priority habitats and species.
In particular this study is focused on the coastal zone between Marina di Tarquinia and Macchia Tonda in the northern Latium region of Italy (Fig. 1B) including Civitavecchia city, where all the above mentioned uses could produce potential conflicts. The Civitavecchia harbor is one of the largest in Europe in terms of cruise and ferry traffic; it represents a fundamental point of commercial exchange in Europe. Thanks to the new Port Regulating Plan, the Port of Civitavecchia has increased its commercial traffic and cruise passenger flow. The Interministerial Committee for Economic Planning (CIPE) approved the final project for the ’strengthening of Civitavecchia harbor hub – first parcel functional interventions: Cristoforo Colombo embankment extension, ferries and services docks realization’. All of these operations involve the handling of significant quantities of sediments; the impacts of dredging on the adjacent natural ecosystems can be varied and difficult to predict (Nayar et al., 2007; Windom, 1976; Cheung and Wong, 1993; Lohrer and Wetz, 2003; Zimmerman et al., 2003; Nayar et al., 2007). Many studies have recently focused on the importance of management of dredged sediments in harbour areas (Cappucci et al., 2011; Cutroneo et al., 2014; Bigongiari et al., 2015). In conflict with the port activities, the study area hosts four SCIs. They are characterized by the presence of habitats (Posidonia oceanica meadows and reefs of rocky substrates and biogenic concretions) and species (Pinna nobilis and Corallium rubrum) enclosed in the attachment 1 and 2 of the European Union (EU) directive 92/43/EEC.

Moreover, the promotion of underwater natural beauty, touristic exploitation connected to the increased cruise traffic and the realization of suitable new bathing facilities have led to a drastic increase in the population density in Civitavecchia during the summer. Many services are now available for recreation thanks to the several beach licenses granted for food, bathing, mooring of private vessels, and sport activities. An updated list of the Latium Region Office counts 72 beach licences released in 2014 to the municipal districts of Santa Marinella and Civitavecchia. However, this urban development was not associated with an upgrade improvement of the wastewater treatment plant, which often caused the discharge of untreated water into the bathing areas. Along the coast, between Civitavecchia harbor and the Punta del Pecoraro bathing areas, four discharge points have been identified as shown in Fig. 1C in conflicts with the recreational use of the coastal zone. These discharge points present high concentrations of pathogenic bacteria deriving from that have been potentially affected by fecal contamination episodes.
3 Components of the C-CEMS

C-CEMS is a multi-platform observing system implemented in 2005 to face the coastal conflicts by an ecosystem-based approach. Accordingly to the Copernicus program, C-CEMS provides a monitoring service for the marine environment through multi-source data including in-situ and remote sensing observations. In addition, C-CEMS integrates this information within mathematical models that allow to simulate specific events and forecast potential impacts with a high spatial and temporal resolution, necessary to analyse the conflicts in coastal areas (Bonamano et al., 2015b).

The workflow reported in fig. 2 shows the interaction between the C-CEMS components and its functioning within the Driver-Pressure-State-Impact-Response (DPSIR) scheme. C-CEMS allows to assess the coastal pressures (Pressure) through the analysis of the dispersion of pollutants connected to the anthropic activities of the Civitavecchia area. It also enables to obtain thematic maps giving information about the sensitivity areas (State) represented mainly by marine protected areas and zones designated for recreational uses (bathing, diving, watersports, fishing, etc.). The overlap between them gives a fundamental contribution for GES achievement and MSP implementation, playing also a crucial role for the detection of the ongoing conflicts. If a conflict occurs, C-CEMS helps in the analysis of its potential impacts (Impact) on environment and socio-economical resources, supporting the choice of the best mitigation practices to be applied (Response).

The workflow indicates also all of the components of the C-CEMS which are described in detail in the following paragraphs.

As shown in Fig. 2, C-CEMS components interact between them to assess the coastal pressures analysing the dispersion of pollutant substances coming from the anthropic activities located along the Civitavecchia coastal area. Data provided by fixed stations, in-situ surveys, and remote sensing play a crucial role being used as input (I = input in Fig. 2) and for the validation (V = validation in Fig. 2) of the numerical models. They give a fundamental contribution in C-CEMS allowing to forecast the dispersion of pollutant substances within the sensitivity areas represented mainly by marine protected areas and zones designated for recreational uses (bathing, diving, watersports, fishing, etc.). To analyse the potential conflicts between the pressures on both marine coastal environment and human health, the results of
the pollutants dispersion, obtained under different weather conditions, are overlapped with the thematic maps of the sensitivity areas.

Since marine coastal ecosystems have been acknowledged as providing the most benefits among all terrestrial and marine ecosystems (Costanza et al., 1997), the appointment of an economic value to these natural resources is essential for correct planning of marine coastal areas. Nevertheless the economic impact on the natural capital in terms of losses of ecosystem goods and services has not been evaluated in this work.

The block diagram (Fig. 2) shows all of the components of the C-CEMS that are outlined in the following paragraphs.

Fixed stations: The capacity of time series data collection is fundamental to improve the ability to control and forecast spatial and temporal variations in a marine environment. To this end, different fixed stations were installed along the Civitavecchia coast to acquire physical, chemical, and biological data, as shown in Fig.1. In particular, a weather station (WS) acquires every 10 min wind speed, wind direction, air temperature, air pressure, humidity and solar radiation. The wind speed and direction represent the main forcing of the hydrodynamic model while the solar radiation data are used as input in the water quality model. Two buoys (WB1 offshore, WB2 nearshore) measure every 30 min wave statistical parameters (significant height, peak period, and mean direction). The wave model is fed with WB1 data and then validated with the wave height data collected by WB2. An Acoustic Doppler Profiler, ADP (WCS), deployed in a Barnacle seafloor platform, acquires both current (with an acquisition rate of 20 min) and wave height and direction (at intervals of 3 h). The current velocity components are employed for the validation of the hydrodynamic model. Three water quality fixed stations, one buoy (Water Quality Buoy, WQB) outside the Civitavecchia harbor and two coastal stations (WQS1 and WQS2), make it possible to acquire every 20 min superficial sea temperature, conductivity (salinity, density), pH, dissolved oxygen, fluorescence of chlorophyll-a, and turbidity. In order to validate the satellite ocean color data, chlorophyll-a (Chla) and total suspended matter (TSM) data acquired by WQB were calibrated with the concentrations obtained by the water samples analyses. The physical and biological parameters of the WQS1 and WQS2, as well as those acquired by satellite observations, are used as initial conditions of the water quality model.

WQB and WQS data are processed following the SeaDataNet parameter quality control procedures: daily validated datasets are produced in order to monitor in near real time the
water quality. Edios xml files are provided for monthly time series and stored following ISO 19139 and ISO 19115 formats provided for metadata.

In-situ surveys: A spatial extension of the observatory system is provided by in-situ collected data. The sampling strategy was conceived within the scope and context of the project objectives in order to select the most appropriate and efficient sampling approach. The field surveys typically include periodic and ad-hoc activities. The firsts concern the measurement acquisition of the physical, chemical and biological variables of the water column using performed by multiparametric probes and sea water samples. Data acquired during periodic surveys are used to validate and integrate the satellite observations in order to give the spatial distributions of the seawater parameters as the initial conditions of the water quality model. The ad-hoc samplings are carried out in order to define the nature and composition of the sea bottom and to analyse the indicators of pollution near the human activities outputs. These data feed the water quality model for the estimate of the bottom shear stress, as well as the dispersion and/or the decay of pollutants in the nearshore coastal waters.

Satellite observations: Remote sensing data are essential to provide synoptic and extensive maps of biological and physical properties of the oceans (Schofield et al., 2002). Recently Earth Observation (EO) data are also used to investigate the dynamic processes at high spatial resolution along the Italian coasts (Filipponi et al., 2015; Manzo et al., 2015). Few studies, among which Cristina et al. (2015), demonstrated the usefulness of remote sensing to support the MSFD, using MEdiun Resolution Imaging Spectrometer (MERIS) sensor products. Similarly we exploited both ocean color from the Moderate Resolution Imaging Spectroradiometer (MODIS) sensor and thermal infrared color from the Advanced Very High Resolution Radiometer (AVHRR) to obtain daily Chla, TSM and sea surface temperature (SST) data. Such sensors data were chosen for their availability both in the region of interest and in the period of C-CEMS data acquisition.

Regarding the AVHRR data, they are downloaded from the NOAA website as a Local Area Coverage (LAC) dataset, at a resolution of 1.1 km. These data are processed using ENVI software, which computes SST images in degrees Celsius, using AVHRR bands 3, 4, and 5 and applying the Multi-Channel Sea Surface Temperature (MCSST) algorithms (Pichel et al., 2001).

Regarding the MODIS data, we download from the NASA website and process by the SeaDAS image analysis package that is freely distributed to users by NASA. The processing
begins with a Level-1A file containing top of the atmosphere (TOA) radiance values recorded by the satellite radiometer. The second step is the Level-2 processing which takes the TOA radiance intensities in the Level-1A file and performs atmospheric corrections to derive a Level-2 file of normalized water leaving radiances (nLw), Chla concentration, geophysical parameters and quality-control flags. A third step takes the geophysical data contained in the Level-2 file and maps it from the raw satellite perspective to a cylindrical coordinate system.

To estimate Chla concentration, MedOC3 bio-optical algorithm is applied (Santoleri et al., 2008, Qin et al., 2007; Santoleri et al., 2008), while TSM estimation is derived from the 645 normalized water-leaving radiance (645 nLw) by applying the MUMM NIR atmospheric correction (Ruddick et al., 2006; Ondrusek et al., 2012).

Finally, Chla and TSM data collected by WQB and periodic in-situ surveys are used to validate the algorithms used for remote sensing data. A work is in progress to implement a local algorithm specifically developed in the area of interest (CASE II waters) in order to reach a better quantification of Chla and TSM concentrations along the study area (Cui et al., 2014). Accordingly with the Copernicus vision, the future development of this module considers to integrate EO data coming from the Optical High-Resolution Sentinel sensors (Drusch et al., 2012), in order to increase the spatial resolution for a more accurate analysis of coastal dynamic processes.

Numerical models: Mathematical models play a key role in the C-CEMS enabling by making it possible to analyse coastal processes at high spatial and temporal resolution. In this context, the entire datasets collected by fixed stations, satellite observations, and in-situ samplings were employed as input conditions and as a validation of the numerical simulations. The mathematical models used in C-CEMS included the DELFT3D package, specifically DELFT3D-FLOW (Lesser et al., 2004) to calculate marine currents velocity, SWAN (Booij et al., 1999) to simulate the wave propagation toward the coast, and DELFT3D-WAQ (Van Gils et al., 1993; Los et al., 2004) to reproduce the dispersion of conservative and non-conservative substances. The governing equations of these models are described in detail in Lesser et al. (2004) and Bonamano et al. (2015a).

The DELFT3D-FLOW model domain is rectangular and covers 70 km of coastal area with the Civitavecchia port located at the center. We applied Neumann boundary conditions on the cross-shore boundaries in combination with a water-level boundary on the seaward side, which is necessary to ensure that the solution of the mathematical boundary
value problem is well-posed. Since small errors may occur near the boundaries, we positioned the study area away from the side of the model domain. The hydrodynamic equations were solved on a finite difference curvilinear grid with approximately 39,000 elements. In order to limit computational requirements, we applied a different resolution in the model domain extending from 15 × 15 m in the Civitavecchia harbor area to 300 × 300 m near the seaward boundary. We subdivided the water column in the vertical direction into 10 sigma layers with a uniform thickness to ensure sufficient resolution in the near-coastal zone.

Since dynamical processes occurring in coastal areas are modulated by wind and wave conditions (we neglect tidal forcing because it does not exceed 0.40 m over the simulation periods), we obtained the hydrodynamic field by coupling the DELFT3D-FLOW with SWAN that uses the same computational grid. Wind data collected by WS were used to feed DELFT3D-FLOW, and the wave parameters acquired by WB1 (offshore wave buoy) were employed to generate the JONSWAP wave spectra (Hasselmann et al., 1980) as boundary conditions of the SWAN model.

To resolve the turbulent scale of motion, the values of horizontal background eddy viscosity and diffusivity were both set equal to 1 m$^2$s$^{-1}$ (Briere et al., 2011), and the k-ε turbulence closure model was taken into account (Launder and Spalding, 1974). To assign the spatial patterns of physical and biological parameters as initial conditions of DELFT3D-WAQ, the satellite observations in the offshore zone and the WQS measures in the nearshore one were used respectively. These data were integrated in the water quality model applying the DINEOF technique (Beckers et al., 2006; Volpe et al., 2012) that reconstructs the missing data along the coast and in the areas affected by clouds.

Since the pollutants dispersion represents the C-CEMS results, the capability of the observation system in reproducing the output of coastal pressures has been evaluated comparing the model results with sea currents (WQB) and wave (WB2) data.

The performance of the hydrodynamic models (DELFT3D-FLOW and SWAN) was evaluated using the Relative Mean Absolute Error (RMAE) and the associated qualitative ranking (excellent, good, reasonable, and poor) (Van Rijn et al., 2003).

The marine currents resulting from the coupling between DELFT3D-FLOW and SWAN were compared with in-situ measurements collected by WCS from 13–18 January 2015. The velocity magnitude was reproduced with a 'good' accuracy since the RMAE value was less
than 0.2. The long-shore and cross-shore components of the marine currents exhibited a higher RMAE: 0.28 and 0.3, respectively. The validation of current speed, cross-shore, and along-shore components is shown in Fig. 3.

We evaluated the performance of the SWAN model using data acquired by the WB2. We calculated the RMAE both for the entire dataset and for three wave direction intervals: 139–198°N (1st interval), 198–257°N (2nd interval), and 257–316°N (3rd interval). Considering the entire dataset, the wave height has been accurately simulated (RMAE<0.1), but the model error changed significantly on the basis of the wave direction: the RMAE is higher between 139°N and 198°N (0.26; reasonable agreement) and lower in the 2nd and 3rd intervals (<0.01; excellent agreement), as reported in Fig. 4.

4 C-CEMS Applications

To test the capabilities of C-CEMS in defining the areas mainly affected by pollutants dispersion, we considered two case studies which concerned the potential effects produced by untreated wastewater discharge and dredging activities (coastal pressures) on bathing areas and SCIs (sensitivity areas), respectively. For both cases two scenarios with different weather conditions are considered: one reproduces a low wind intensity and low wave height (low condition, LC), and the other simulates a strong high wind speed and high wave height (high condition, HC).

4.1 Bacterial dispersion in bathing areas

The presence of pathogenic bacteria in seawater may cause several illnesses including skin infections and dangerous gastrointestinal diseases (Cabelli et al., 1982; Cheung et al., 1990; Calderon et al., 1991; McBride et al., 1998; Haile et al., 1999; Colford et al., 2007). The probability of human infection depends on the exposure time and the concentration of the bacterial load in bathing areas. These parameters are linked to the presence of untreated wastewater discharge in the study area and the local hydrodynamical (currents and waves) and environmental (salinity, temperature, and solar radiation) conditions. Among the bacteria that can damage the health of bathers, *Escherichia coli*, a Gram-negative enteric bacteria present in the feces of humans and warm-blooded animals, is considered to be an indicator of water
quality. Although the pathogenic bacteria are neglected by MSFD, microbes are relevant to several GES descriptors, notably Descriptor 1 (D1, Biological Diversity), Descriptor 4 (D4, Foodwebs), Descriptors 5 (D5, Eutrophication), Descriptor 8 (Contaminants) (Caruso, 2014; Caruso et al., 2015). However, controlling water quality in bathing waters is required by national—National (Legislative Decree d.lgs 116/2008) and community—Community environmental directives (2006/7/CEC).

Within the framework Under the umbrella of C-CEMS to perform provide fecal pollution monitoring, in-situ water samplings were performed—carried out weekly during the summer 2012 at the discharge points indicated in Fig. 1C to analyse the abundance of E. coli according to standard culture methods (APAT CNR, 2003).

To define the zones mainly affected by the dispersion of pathogenic bacteria in the Civitavecchia bathing area, we used the Microbiological Potential Risk Area (MPRA), defined as the area over which the E. coli concentration is greater or equal to 1% of the concentration measured at a discharge point (Bonamano et al., 2015a). The dispersion of E. coli has been—was simulated by DELFT3D-WAQ using the mean bacterial concentration measured during the summer at the discharge points. This model shows a good performance of in reproducing the bacterial load concentration near the discharge points (Zappalà et al., in press 2015). The LC and HC simulations that last two days were set to occur on August weekends when the beaches are characterized by a larger number of bathers. The distribution of bacterial concentration over the study area calculated by DELFT3D-WAQ over the study area depends—depended on the hydrodynamic field obtained from the coupling between DELFT3D-FLOW and SWAN and on the decay rate proposed by Thoe et al. (2010). It was calculated using the salinity acquired by WQS1, WQS2 and WQB, the surface solar radiation measured by WS, TSM and SST obtained by the integration between satellite observations and WQS stations data.

The E. coli concentration calculated near the discharge points was high when low marine currents (LC) were present, as reported in Fig. 5A. In particular, the area around the PI18 point exhibited maximum values of pathogenic bacteria because of the slow dilution of contaminated waters in that area. During intense weather conditions (HC), the E. coli concentration near the discharge points was lower than that calculated in the LC simulation. However, the bacterial load E. coli concentration was distributed over a more extended area,
as reported in Fig. 5B. In both simulations, the dispersion of *E. coli* did not affect the bathing area located to the south of the study area.

4.2 Dredged sediments dispersion on *Posidonia oceanica* meadows

As previously reported, the port of Civitavecchia has been subjected to extensive dredging between 1 November 2012 and 31 January 2013. During the first phase of the project, the dredging of the channel to access the port of Civitavecchia was conducted by deepening the seabed to a depth of -17 m above mean sea level over an area of approximately 31,000 m². In the ferry dock area, the seabed reached a depth of -10 m over an area of approximately 123,650 m² and -15 m over an area of approximately 51,900 m². The total dredging volume was approximately 918,000 m³.

Studying sediment resuspension caused by these dredging activities is critical because of its role in the dispersion of particulate matter in the adjacent marine environment in both the sediment and water (Van den Berg et al., 2001). Within MSFD, turbidity due to fine sediment dispersion is an indicator reported in Descriptor 1 (D1, Biological biodiversity), Descriptor 5 (D5, Eutrophication) and Descriptor 7 (Hydrographical condition). In this study, we considered two out of the four SCIs coded as IT60000005 (434.47 ha) and IT60000006 (745.86 ha) localized in the north and the south of the Civitavecchia harbor, as shown in Fig. 1B. Since *Posidonia oceanica* makes up most of the SCIs, the study focused on studying the effects of dredging activities on the seagrass status of the seagrass. Dredging-induced suspended sediment transport and deposition may have direct and indirect impacts on this seagrass such as reducing the underwater light penetration and producing the burial of the shoot apical meristems, respectively. The plant survival of the plant can be compromised if the light availability is less than 3–8% of SI (Erftemeijer and Lewis, 2006) or if low-light conditions persist for more than 24 months (Gordon et al., 1994). The survival rates of *Posidonia oceanica* can also be reduced if the sedimentation rate exceeds 5 cm per year (Manzanera et al., 1995).

The health status of *Posidonia oceanica* meadows located in the two SCIs has been evaluated by shoot density descriptor. This parameter was acquired by scuba-divers in the late Spring of 2013 in correspondence of 14 stations (3 in IT60000005 and 11 in IT60000006).
following the method reported in Buia et al. (2003). The thematic map was obtained spatially interpolating the data collected in the two areas.

The potential impacts due to dredging activities have been evaluated by DELFT3D-WAQ simulations assuming a continuous release of fine sediments (< 0.063 mm) in the northern zone of Civitavecchia harbor. The amount of material released during dredging was calculated using a formula from Hayes and Wu (2001) with a resuspension factor of 0.77%, which is typical of hydraulic dredges (Anchor Environmental, 2003). The percentage of fine sediment fraction was 8.87% and its density was 2650 kg m$^{-3}$ according to sedimentological data collected in the area affected by the dredging works. Considering also that the time spent on dredging operations lasted approximately 3 months (from November 2012 until January 2013), we assumed a continuous release of 0.314 kg s$^{-1}$. TSM distribution, obtained by the integration between satellite observations and WQB data, was used as a proxy of spatial variation of fine sediment concentration in the study area to provide the initial conditions of DELFT3D-WAQ. The transport, deposition, and resuspension processes associated with the fine particles was reproduced taking into account a settling velocity of approximately 0.25 m day$^{-1}$, a critical shear for sedimentation of 0.005 N m$^{-2}$, and a critical shear for resuspension of 0.6 N m$^{-2}$ (Alonso, 2010). The DELFT3D-WAQ simulations were run over the periods 26 November 2012 through 3 December 2012 (HC simulation) and 3–10 January 2013 (LC simulation). These time intervals included the dredging period.

Analogous to the analysis of bacterial dispersion, the fate of dredged sediments within the study area was evaluated over an area in which the suspended solid concentration was greater or equal to 1% of the value estimated at the source point. This area was referred to as the Dredging Potential Impact Area (DPIA). The results of the LC simulation, reported in Fig. 6A, revealed that the dredged suspended materials were transported into the southern zone of the study area achieving a maximum distance of approximately 2 km from dredging point. In the HC simulation reported in Fig. 6B, the dredged sediment dispersion moved toward the north with higher concentration in the nearshore zone. Although the sediment plume extended 20 km from the source, higher values of suspended solid concentration only affected the Posidonia oceanica meadow closer to the harbor (the southern part of SCI IT 6000005) (Bonamano et al., 2015b).
5 Discussions

In the last two decades, the importance of integrated ocean observing systems, providing observations, numerical models and software infrastructures, has been widely recognized, not only for scientific purposes but also to support societal needs such as the management of marine resources and the mitigation of anthropic pressures through specific planning (Siddorn et al. 2007; Weisberg et al. 2009; Tintoré 2013; Sayol et al. 2014). Especially in coastal environments where unpredictable pollution phenomena often occur, the set up of multi-platform observing systems represents an important step towards the analysis and forecasting of the impacts on both environmental and socio-economical resources, overcoming the difficulties of the traditional approach (Schofield et al., 2002) which does not allow a proper identification.

In this aim, C-CEMS was implemented in 2005 along the coast of Civitavecchia, which is a highly populated area characterized by the coexistence of industrial and human pressures with environmental resources and values. It integrates fixed stations, in-situ survey and satellite observations which ensure the availability of a large amount of data allowing the analysis of coastal conflicts by the detection of pollution phenomena. Moreover C-CEMS provides an ecosystem-based monitoring tool for the analysis and forecasting of the coastal conflicts thanks to the use of mathematical models. Kourafalou et al. (in press) highlighted the need to support the advancement of coastal forecasting systems integrating the observational and modelling components in order to analyse the high spatial and temporal variability of coastal processes. The results of the hydrodynamic models The validation of hydrodynamic models with sea currents (WCS) and wave (WB2) data, shows how C-CEMS is able to reproduce accurately the output of coastal pressures in terms of pollutants dispersion. DELFT3D-FLOW reproduces with good accuracy the velocity components of marine currents, while SWAN calculates the wave height in the nearshore area with an higher skill when the interval direction is 198-316 °N. On the contrary, when the wave direction ranges between 139 °N and 198 °N, the capacity of the model is more affected by the increase of diffraction processes due to the Civitavecchia harbor breakwater.

Two examples of C-CEMS capacity to provide information related to some of the most pressing conflicts facing our coastal zone, such as "urban discharge - bathing area" and "dredging - SCI", have been reported in this study. The application of C-CEMS to these two case studies examples allowed to define the output of human activities by the use of
'potentially-polluting zoning indicators' such as MPRA and DPIA, giving the potential impacts produced by pathogenic bacteria and dredged fine sediment on sensitivity areas such as MPRAs in bathing zones and the DPIAs on SCIs under different weather conditions (HC and LC). The overlap of the model results with the thematic maps of the sensitivity areas enabled the detection of the coastal areas interested by conflicts.

In the first case, the overlap of MPRAs calculated in LC and HC scenarios shows that most of the bathing areas were affected by high level of bacterial contamination (Fig. 7A). Maximum values of E.coli abundance were found near the PI18 and PP24 discharges because the dilution of the contaminated waters was inhibited by the presence of artificial barriers. These unfavorable conditions may cause possible risks to human health related to the contamination of potentially infectious microorganisms for bathers. As a result, the bathing facilities located within this zone were at risk of suffering significant economic losses. However the southern bathing area, where more bathers are found, was never affected by E. coli dispersion (Fig. 7A).

In the second case study, the simulation results differ among LC and HC scenarios (Fig. 7B). In the LC scenario, DPIA does not overlap the southern SCI (IT 6000006), even though the seagrass meadows were characterized by poorer health than in northern SCI. In HC, DPIA includes a restricted zone of Posidonia oceanica meadow (98.84 ha) in the northern SCI, closer to Civitavecchia harbor, characterized by high shoot density values (between 400 and 550 shoots m$^{-2}$). A previous study (Bonamano et al. 2015b) showed that after the dredging activities the shoot density values were slightly higher than before, highlighting how this conflict did not produce a loss of environmental resources.

These results show how C-CEMS works to give a rapid environmental assessment enabling to analyse the impacts and potential mitigation practices when an user-environment conflict is detected. If there are no conflicts, the system still provides integrated information for the sustainable management of coastal zone as requested by IMP for the EU.

To make C-CEMS more effective, a flexible X-Band Radar System to continuously measure the sea-state (surface currents and wave field) in the near-shore zone (Serafino et al., 2012) has been recently integrated. Moreover, to improve the resolution of multi-spectral imagery in the study area, C-CEMS will be soon available to get data also from Sentinel-2 mission.

Since coastal marine ecosystems have been acknowledged to provide the most benefits among all terrestrial and marine ecosystems (Costanza et al., 1997), the assignment of an economic
value to these natural resources is essential for correct planning of marine coastal areas. The last step toward an adequate management and conservation of marine environmental resources concerns the implementation of C-CEMS for the quantification of economic impacts in terms of losses of ecosystem services and goods.

Compared to other regional operational monitoring systems currently available and reported in the literature, the practical innovation offered by the C-CEMS relies on the fact that this new system allows to detect the impacts arising from the potential conflicts between coastal pressures and sensitivity areas; in this sense C-CEMS can be considered an operational tool to meet the needs of MSFD and MSP directives.

6 Conclusions

The activities and techniques employed are in line with those used in several environmental monitoring experiences; what really is new is their integration into an operational network, the first in the Tyrrhenian sea, actually used by a professional stakeholder as the Port Authority of Civitavecchia.

Coastal observatories play a major role in providing the information needed to face the new European environmental challenges mainly focused on the GES achievement and MSP implementation. Thanks to the integration of different observing platforms at different scales, and to the provision of data and tools, these systems contribute to the monitoring of coastal pressures and environmental states. C-CEMS has been conceived to include all the above mentioned features to support the coastal management about the detection of the conflicts between anthropic pressure and sensitivity areas. Such information overlapped with the characteristics of coastal marine ecosystems intended to recreational uses can be considered as the first step for the establishment of marine functional zoning scheme made by different types of zones with varying levels of limited uses (Douvere, 2008).

The main objective of C-CEMS is to provide an observation system for a rapid environmental assessment and to forecast the coastal dynamic processes at appropriate temporal and spatial resolutions. It can also contribute to the availability of marine observations and coastal data, increasing the knowledge about the environmental status of marine ecosystems. To make C-CEMS more effective, a flexible X Band Radar System to continuously measure the sea state (surface currents and wave field) in the near-shore zone (Serafino et al., 2012) has been
recently integrated. Moreover, to improve the resolution of multi-spectral imagery in the study area, C-CEMS will be soon available to get data also from Sentinel-2 mission.

The final goal of this study was to use C-CEMS to address potential conflicts among the different human activities that persist on the coast using an ecosystem-based approach as requested by IMP for the EU.

C-CEMS allowed to define the output of human activities by the use of 'potentially-polluting zoning indicators' as MPRA and DPIA giving the potential impacts produced by pathogenic bacteria and dredged fine sediment on sensitivity areas. Such information overlapped with the characteristics of recreational coastal uses and marine ecosystems can be considered as the first step for the establishment of marine functional zoning scheme made by different types of zones with varying levels of limited uses (Douvere, 2008).

The last step toward an adequate management and conservation of marine environment resources concerns the quantification of economic impacts related to the losses of ecosystem services and goods through the analysis of the present and future conflicts.

Acknowledgements

The authors thank the Environmental Office of Civitavecchia Port Authority for funding the implementation of C-CEMS. The authors also thank their colleagues for continuing support and discussion around the coffee breaks. The authors are also thankful to two anonymous reviewers for providing useful comments that helped in improving a former version of this manuscript. Finally, the authors acknowledge the NOAA CoastWatch Program and NASA's Goddard Space Flight Center, OceanColor Web for data availability.

Zoom-in on the area of C-CEMS applications: the location of coastal uses, SCIs, and measurement stations indicated (B) and the Civitavecchia bathing areas with discharge points and bather density indicated (1 umbrella corresponds to 5 bathers) (C). The fixed station pictures are reported in the bottom-left corner of the figure. The coordinate system is expressed in UTM 32 (WGS84).
Figure 2. The **functioning role** of C-CEMS for the analysis of the conflicts between coastal pressures, in terms of pollutant dispersion, and sensitivity areas, represented by thematic maps. This observing system includes different components such as fixed stations, in-situ surveys, satellite observations and numerical models. The C-CEMS components interact between them to transfer data (by input (I) and validation (V)) from the in-situ and satellite observations to numerical models in order to reach **enough** temporal and spatial resolution **enough** to analyse the pollutants dispersion in coastal waters. The conflicts are evaluated overlapping the model results with the thematic maps of the sensitivity areas. The economic impact of the conflicts on the marine environment and human health is reported, even though it is not analysed in this work. Only if conflicts between anthropic activity and sensitivity areas occur, the potential impacts on environment and socio-economical resources are analysed (Impacts) and suitable mitigation measures are applied (Response) in order to achieve Good Environmental Status (GES) and implement Marine Spatial Planning (MSP).
