Interactive comment on “Understanding mixing efficiency in the oceans: do the nonlinearities of the equation of state for seawater matter?” by R. Tailleux

R. Tailleux
r.g.j.tailleux@reading.ac.uk

Received and published: 11 March 2009

I am aware that the present manuscript is difficult to understand without access to my other manuscript (Tailleux, 2008). I had hoped that the latter could have been made available as supplementary material. As this is not possible, I have uploaded the manuscript to the ArXiv service, so that the manuscript is now available anonymously at the following address:

The manuscript is also available on my web page at: http://www.met.reading.ac.uk/~remi/publications
I have taken note of the other comments. I agree that I could probably improve the manuscript clarity with some effort, and I am ready to do that to facilitate the reading of the paper. $D(\text{APE})$ is the diffusive dissipation of Available potential Energy. The subscript $r$ refers to the background reference state, as defined by Lorenz (1955). With regard to $G(\text{KE})$, its definition is provided just before equation 3 as: "the work done by the mechanical sources of stirring" (Munk and Wunsch (1998) assume that $G(\text{KE})=D(\text{KE})$, i.e., that the rate of mechanical energy input $G(\text{KE})$ is balanced by viscous dissipation $D(\text{KE})$).

I hope that this contributes to clarify things.
